1. COUNTING UNIPOTENT REPRESENTATIONS

In this section, let $G_{\mathbb{C}}$ be a connected complex reductive group and \mathfrak{g} is its Lie algebra. Fix a antiholomorphic involution σ on $G_{\mathbb{C}}$ and a corresponding Cartan involution θ of $G_{\mathbb{C}}$. Let G be a finite central extension of a open subgroup of $G_{\mathbb{C}}^{\sigma}$ and

$$\text{pr}: G \rightarrow G_{\mathbb{C}}^{\sigma}$$

be the canonical projection. Let $K = \text{pr}^{-1}(G_{\mathbb{C}}^{\sigma})$ and $W = W(G_{\mathbb{C}})$.

Let ${}^a\mathfrak{h}$ be the abstract Cartan subalgebra of \mathfrak{g} and aX be the lattice of abstract weight spaces. Let ${}^aR \subseteq {}^aX$, ${}^aR^+$ and aQ be the abstract root system, the set of positive roots and the root lattice. Let

$$\mathbb{C} = \left\{ \mu \in {}^a\mathfrak{h}^* \mid \begin{array}{l} \text{either } \langle \text{Re}(\mu), \check{\alpha} \rangle > 0 \text{ or} \\ \langle \text{Re}(\mu), \check{\alpha} \rangle = 0 \text{ and } \sqrt{-1} \langle \text{Im}(\mu), \check{\alpha} \rangle > 0 \end{array} \right\}$$

and $\overline{\mathbb{C}}$ be the closure of \mathbb{C} in ${}^a\mathfrak{h}$.

We identify the set of infinitesimal characters with ${}^a\mathfrak{h}^*/W$.

1.1. Coherent family. For each finite dimensional \mathfrak{g} -module or $G_{\mathbb{C}}$ -module F , let F^* be its contragredient representation and let $\Delta(F) \subseteq {}^aX$ denote the multi-set of weights in F .

Let $\Pi_{\Lambda_0}(G_{\mathbb{C}})$ be the set of irreducible finite dimensional representations of $G_{\mathbb{C}}$ with external weight in Λ_0 and $\mathcal{G}_{\Lambda}(G_{\mathbb{C}})$ be the subgroup generated by $\Pi_{\Lambda_0}(G_{\mathbb{C}})$. Let

$${}^aP := \{ \mu \in {}^aX \mid \mu \text{ is a } {}^a\mathfrak{h}\text{-weight of an } F \in \Pi_{\text{fin}}(G_{\mathbb{C}}) \}.$$

Via the highest weight theory, every W -orbit $W \cdot \mu$ in aP corresponds with the irreducible finite dimensional representation $F \in \Pi_{\text{fin}}(G_{\mathbb{C}})$ with external weight μ .

Now the Grothendieck group $\mathcal{G}(G_{\mathbb{C}})$ of finite dimensional representation of $G_{\mathbb{C}}$ is identified with $\mathbb{Z}[{}^aP/W]$. In fact $\mathcal{G}(G_{\mathbb{C}})$ is a \mathbb{Z} -algebra under the tensor product and equipped with the involution $F \mapsto F^*$.

Fix a W -invariant sub-lattice $\Lambda_0 \subset {}^aX$ containing aQ .

2000 *Mathematics Subject Classification.* 22E45, 22E46.

Key words and phrases. orbit method, unitary dual, unipotent representation, classical group, theta lifting, moment map.

Take a lattice $\Lambda = \lambda + \Lambda_0 \in \mathfrak{h}^*/\Lambda$ with $\lambda \in \overline{\mathbb{C}}$. Let

$$R(\lambda) := \{ \alpha \in {}^a R \mid \langle \lambda, \check{\alpha} \rangle \in \mathbb{Z} \} \quad \text{and} \quad W(\lambda) := \langle s_\alpha \mid \alpha \in R(\lambda) \rangle.$$

Definition 1.1. Suppose \mathcal{M} is an abelian group with $\mathcal{G}_\Lambda(G_\mathbb{C})$ -action

$$\mathcal{G}_\Lambda(G_\mathbb{C}) \times \mathcal{M} \ni (F, m) \mapsto F \otimes m.$$

In addition, we fix a subgroup $\mathcal{M}_{[\mu]}$ of \mathcal{M} for each W -coset $[\mu] \in \Lambda/W$.

A function $f: \Lambda \rightarrow \mathcal{M}$ is called a coherent family based on Λ if it satisfies $f(\mu) \in \mathcal{M}_\mu$ and

$$F \otimes f(\mu) = \sum_{\nu \in \Delta(F)} f(\mu + \nu) \quad \forall \mu \in \Lambda, F \in \Pi_{\Lambda_0}(G_\mathbb{C}).$$

Let $\text{Coh}_\Lambda(\mathcal{M})$ be the abelian group of all coherent families based on Λ and value in \mathcal{M} .

In this paper, we will consider the following cases.

Example 1.2. Suppose $\mathcal{M} = \mathbb{Q}$ and $F \otimes m = \dim(F) \cdot m$ for $F \in \Pi_{\Lambda_0}(G_\mathbb{C})$ and $m \in \mathcal{M}$. We let $\mathcal{M}_\mu = \mathcal{M}$ for every $\mu \in \Lambda$. When $\Lambda = \Lambda_0$, the set of W -harmonic polynomials on ${}^a \mathfrak{h}^*$ is naturally identified with $\text{Coh}_\Lambda(\mathcal{M})$ via restriction (Vogan's result)

Example 1.3. Let $\mathcal{G}(\mathfrak{g}, K)$ be the Grothendieck group of finite length (\mathfrak{g}, K) -modules and $\mathcal{G}_\mu(\mathfrak{g}, K)$ be the subgroup of $\mathcal{G}(\mathfrak{g}, K)$ generated by the set of irreducible (\mathfrak{g}, K) -modules with infinitesimal character μ .

Then $\text{Coh}_\Lambda(\mathcal{G}(\mathfrak{g}, K))$ is the group of coherent families of Harish-Chandra modules.

Example 1.4. Fixing a Borel subalgebra $\mathfrak{b} \subset \mathfrak{g}$, let $\mathcal{G}(\mathfrak{g}, \mathfrak{b})$ be the Grothendieck group of the category $\mathcal{O}^{\mathfrak{b}}$. The space $\text{Coh}_\Lambda(\mathcal{G}(\mathfrak{g}, \mathfrak{b}))$ is defined similarly.

Note that the lattice Λ is stable under the $W(\lambda)$ action. We can define $W(\lambda)$ action on $\text{Coh}_\Lambda(\mathcal{M})$ by

$$w \cdot f(\mu) = f(w^{-1}\mu) \quad \forall \mu \in \Lambda, w \in W(\lambda).$$

Translation principal assumption. Recall that we have fixed a set of simple roots of W_Λ . We make the following assumption for $\text{Coh}_\Lambda(\mathcal{M})$.

- There is a basis $\{\Theta_\gamma \mid \gamma \in \text{Parm}\}$ of $\text{Coh}_\Lambda(\mathcal{M})$ where Parm is a parameter set;
- For every $\mu \in \Lambda$, the evaluation at μ is surjective;

$$\text{ev}_\mu: \text{Coh}_\Lambda(\mathcal{M}) \rightarrow \mathcal{M}_{[\mu]} \quad f \mapsto f(\mu)$$

is surjective;

- a subset $\tau(\gamma)$ of the simple roots of W_Λ is attached to each $\gamma \in \text{Parm}$ such that $s \cdot \Theta_\gamma = -\Theta_\gamma$;
- $\Theta_\gamma(\mu) = 0$ if and only if $\tau(\gamma) \cap R_\mu \neq \emptyset$.
- $\{\Theta_\gamma(\mu) \mid \tau(\gamma) \cap R_\mu = \emptyset\}$ form a basis of \mathcal{M}_γ .

The translation principle assumption implies

$$(1.1) \quad \text{Ker ev}_\mu = \text{span} \{ \Theta_\gamma \mid \tau(\gamma) \cap R_\mu \neq \emptyset \}$$

Now we have the following counting lemma.

Lemma 1.5. For each μ , we have

$$\dim \mathcal{M}_{[\mu]} = \dim(\text{Coh}_\Lambda(\mathcal{M}))_{W_\mu} = [\text{Coh}_\Lambda(\mathcal{M}), 1_{W_\mu}].$$

Proof. Clearly

$$\text{span} \{ \Theta_\gamma - w\Theta_\gamma \mid \gamma \in \text{Parm}, w \in W_\Lambda \} \subseteq \text{ker ev}_\mu$$

since $w \cdot \Theta_\gamma(\mu) = \Theta_\gamma(w^{-1} \cdot \mu) = \Theta_\gamma(\mu)$ for $w \in W_\mu$. Combine this with (1.1), we conclude that

$$\text{span} \{ \Theta_\gamma - w\Theta_\gamma \mid \gamma \in \text{Parm}, w \in W_\Lambda \} = \text{ker ev}_\mu.$$

Therefore, ev_μ induces an isomorphism $(\text{Coh}_\Lambda(\mathcal{M}))_{W_\mu} \rightarrow \mathcal{M}_{[\mu]}$. Now the dimension equality follows. \square

Example 1.6. *For the case of category \mathcal{O} . We can take $\text{Parm} = W_\Lambda$. Let $\Theta_w(\mu) = L(w\mu)$ for each $w \in W_\Lambda$ with $\tau(w) = \{s_\alpha \mid \alpha \in \Delta^+, w\alpha \notin R^+\}$.*

Example 1.7. *In the Harish-Chandra module case, Parm consists of certain irreducible K -equivariant local systems on a K -orbit of the flag variety of G . $\tau(\gamma)$ is the τ -invariants of the parameter γ .*

2. PARAMETERIZE OF UNIPOTENT REPRESENTATIONS

We fix an abstract complex Cartan subgroup \mathbf{H}_a and \mathfrak{h}_a in \mathbf{G} and a set of simple roots Π_a . Let $\mathcal{P}(\mathbf{G})$ be the set of all Langlands parameters of G -modules with character ρ (i.e. the infinitesimal character of the trivial representation). For $\gamma \in \mathcal{P}(\mathbf{G})$, let $\mathcal{L}(\gamma)$, $\mathcal{S}(\gamma)$ and Φ_γ be the corresponding Langlands quotient, standard module and coherent family such that $\Phi_\gamma(\rho) = \mathcal{L}(\gamma)$. Let $\mathcal{M}(\mathbf{G})$ be the span of $\mathcal{L}(\gamma)$. Let $\{\mathcal{B}\}$ be the set of all blocks. Then $\mathcal{P}(\mathbf{G}) = \bigsqcup_{\mathcal{B}} \mathcal{B}$. The Weyl group $W = W(G)$ acts on $\mathcal{M}(\mathbf{G})$ by coherent continuation. Let $\mathcal{M}_{\mathcal{B}}$ be the submodule of $\mathcal{M}(\mathbf{G})$ spanned by $\gamma \in \mathcal{B}$, then

$$\mathcal{M}(\mathbf{G}) = \bigoplus_{\mathcal{B}} \mathcal{M}_{\mathcal{B}}$$

Let $\tau(\gamma) \subset \Pi_a$ be the τ -invariant of γ .

Let \mathcal{O} be even orbit. $\lambda = \frac{1}{2}\check{h}$. Define

$$S(\lambda) = \{ \alpha \in \Pi_a \mid \langle \alpha, \lambda \rangle = 0 \}.$$

Let $\mathcal{P}_\lambda(\mathbf{G})$ be the set of all Langlands parameters with infinitesimal character λ . Let $T_{\lambda,\rho}$ be the translation functor. Let

$$\mathcal{B}(S) = \{ \gamma \in \mathcal{B} \mid S \cap \tau(\gamma) = \emptyset \}$$

and

$$\mathcal{P}(\mathbf{G}, S) = \bigsqcup_{\mathcal{B}} \mathcal{B}(S)$$

Then

$$\begin{aligned} \mathcal{P}(\mathbf{G}, S) &\longrightarrow \mathcal{P}_\lambda(\mathbf{G}) \\ \gamma &\longmapsto T_{\lambda,\rho}(\gamma) \end{aligned}$$

Let \mathcal{O} be a complex nilpotent orbit in \mathfrak{g} . Let

$$\mathcal{B}(S, \mathcal{O}) = \{ \gamma \in \mathcal{B}(S) \mid \text{AV}_{\mathbb{C}}(\mathcal{L}(\gamma)) \subset \overline{\mathcal{O}} \}$$

Let

$$\begin{aligned} m_S(\sigma) &= [\sigma : \text{Ind}_{W(S)}^W \mathbf{1}] \\ m_{\mathcal{B}}(\sigma) &= [\sigma : \mathcal{M}_{\mathcal{B}}] \end{aligned}$$

Barbasch [10, Theorem 9.1] established the following theorem.

Theorem 2.1.

$$|\mathcal{B}(S, \mathcal{O})| = \sum_{\sigma} m_{\mathcal{B}}(\sigma) m_S(\sigma)$$

Here $\sigma \times \sigma$ running over the $W \times W$ appears in the double cell $\mathcal{C}(\mathcal{O})$.

Proof. We need to take the graded module of $\mathcal{M}(\mathbf{G})$ with respect to the $\overset{LR}{\leq}$. By abuse of notation, we identify the basis $\mathcal{P}(\mathbf{G})$ with its image in the graded module. Note that $S \cap \tau(\lambda) = \emptyset$ if and only if $W(S)$ acts on γ trivially by [70, Lemma 14.7]. On the other hand, by [70, Theorem 14.10, and page 58], $\text{AV}_{\mathbb{C}}(\mathcal{L}(\gamma)) \subset \overline{\mathcal{O}}$ only if γ generate a W -module in the double cell of \mathcal{O} . \square

Now assume $S = S(\lambda)$. By [12, Cor 5.30 b) and c)], $[\sigma : \text{Ind}_{W(S)}^W \mathbf{1}] = [\mathbf{1}|_{W(S)} : \sigma] \leq 1$.

3. COUNTING IN TYPE A

The results in this section are well known to the experts.

Let \mathbf{YD} be the set of Young diagrams viewed as a finite multiset of positive integers. The set of nilpotent orbits in $\text{GL}_n(\mathbb{C})$ is identified with Young diagram of n boxes.

Let $\check{G}_{\mathbb{C}} = \text{GL}_n(\mathbb{C})$. Fix an orbit $\check{\mathcal{O}} \in \text{Nil}(ckG)$, let $\check{\mathcal{O}}_e$ (resp. $\check{\mathcal{O}}_o$) be the partition consists of all even (resp. odd) rows in $\check{\mathcal{O}}$.

Let S_n denote the Weyl group of $\text{GL}_n(\mathbb{C})$. Let $W_n := S_n \ltimes \{\pm 1\}^n$ denote the Weyl group of type B_n or C_n . Let sgn denote the sign representation of the Weyl group. The group W_n is naturally embeded in S_{2n} . For W_n , let ϵ denote the unique non-trivial character which is trivial on S_n . Note that ϵ is also the restriction of the sgn of S_{2n} on W_n .

3.1. Special unipotent representations of $G = \text{GL}_n(\mathbb{C})$. By [12], the set of unipotent representations of $G = \text{GL}_n(\mathbb{C})$ one-one corresponds to nilpotent orbits in $\text{Nil}(\check{G}_{\mathbb{C}})$. Suppose $\check{\mathcal{O}}$ has rows

$$\mathbf{r}_1(\check{\mathcal{O}}) \geq \mathbf{r}_2(\check{\mathcal{O}}) \geq \cdots \geq \mathbf{r}_k(\check{\mathcal{O}}) > 0.$$

Then $\mathcal{O} := d_{\text{BV}}(\check{\mathcal{O}})$ has columns $\mathbf{c}_i(\mathcal{O}) = \mathbf{r}_i(\check{\mathcal{O}})$ for all $i \in \mathbb{N}^+$. The map $\check{\mathcal{O}} \mapsto \mathcal{O}$ is a bijection.

We set $\mathbf{CP} = \mathbf{YD}$ be the set of Young diagrams. For $\tau \in \mathbf{CP}$ which has k columns, let $1_{\mathbf{c}}$ be the trivial representations of $\text{GL}_{\mathbf{c}}(\mathbb{C})$.

$$\pi_{\tau} = 1_{\mathbf{c}_1(\tau)} \times 1_{\mathbf{c}_2(\tau)} \times \cdots \times 1_{\mathbf{c}_k(\tau)}.$$

The Vogan duality gives a duality between Harish-Chandra cells. In this case, Harish-Chandra cells is the double cell of Lusztig. Now we have a duality

$$\pi_{\tau} \leftrightarrow \pi_{\tau^t}.$$

Let $\tau' := \nabla(\tau)$ be the partition obtained by deleting the first column of τ . Let $\theta_{a,b}$ (resp. $\Theta_{a,b}$) be the theta lift (resp. big theta lift) from $\text{GL}_a(\mathbb{C})$ to $\text{GL}_b(\mathbb{C})$. Then we have

$$\pi_{\tau} = \theta_{|\tau'|, |\tau|}(\pi_{\tau}).$$

3.2. Counting unipotent representations of $\text{GL}_n(\mathbb{R})$. Now let $\check{\mathcal{O}} \in \text{Nil}(\check{G}_{\mathbb{C}})$. Recall the decomposition $\check{\mathcal{O}} = \check{\mathcal{O}}_e \cup \check{\mathcal{O}}_o$. Let $n_e = |\check{\mathcal{O}}_e|$, $n_o = |\check{\mathcal{O}}_o|$ and $\lambda_{\check{\mathcal{O}}} = \frac{1}{2}\check{h}$.

Then

$$\begin{aligned} W(\lambda_{\check{\mathcal{O}}}) &\cong S_{|\check{\mathcal{O}}_e|} \times S_{|\check{\mathcal{O}}_o|}. \\ W_{\lambda_{\check{\mathcal{O}}}} &= \prod_j S_{\mathbf{c}_j(\check{\mathcal{O}}_e)} \times \prod_j S_{\mathbf{c}_j(\check{\mathcal{O}}_o)} \end{aligned}$$

By the formula of a -function, one can easily see that The cell in $W(\lambda_{\check{\mathcal{O}}})$ consists of the unique representatoin $J_{W_{\lambda_{\check{\mathcal{O}}}}}^{W[\lambda_{\check{\mathcal{O}}}]}(1)$. Now the W -cell is $J_{W_{\lambda_{\check{\mathcal{O}}}}}^W 1$ corresponds to the orbit $\mathcal{O} = \check{\mathcal{O}}^t$ under the Springer correspondence. [**WLOG, we assume $\check{\mathcal{O}} = \check{\mathcal{O}}_o$.**

Let $\sigma \in \widehat{S}_n$. We identify σ with a Young diagram. Let $c_i = \mathbf{c}_i(\sigma)$. Then $\sigma = J_{W'}^{S_n} \epsilon_{W'}$ where $W' = \prod S_{c_i}$ (see Carter's book). This implies Lusztig's a -function takes value

$$a(\sigma) = \sum_i c_i(c_i - 1)/2$$

Comparing the above with the dimension formula of nilpotent Orbits [17, Collary 6.1.4], we get (for the formula, see Bai ZQ-Xie Xun's paper on GK dimension of $SU(p, q)$)

$$\frac{1}{2} \dim(\sigma) = \dim(L(\lambda)) = n(n-1)/2 - a(\sigma).$$

Here $\dim(\sigma)$ is the dimension of nilpotent orbit attached to the Young diagram of σ (it is the Springer correspondence, regular orbit maps to trivial representation, note that $a(\text{triv}) = 0$), $L(\lambda)$ is any highest weight module in the cell of σ .

Return to our question, let $S' = \prod_i S_{\mathbf{c}_i(\check{\sigma})}$. We want to find the component σ_0 in $\text{Ind}_{S'}^{S_n} 1$ whose $a(\sigma_0)$ is maximal, i.e. the Young diagram of σ_0 is minimal.

By the branching rule, $\sigma \subset \text{Ind}_{S'}^{S_n} 1$ is given by adding rows of length $\mathbf{c}_i(\check{\sigma})$ repeatedly (Each time add at most one box in each column). Now it is clear that $\sigma_0 = \check{\sigma}^t$ is desired.

This agrees with the Barbasch-Vogan duality d_{BV} given by

$$\check{\sigma} \xrightarrow{\text{Springer}} \check{\sigma} \xrightarrow{\otimes \text{sgn}} \check{\sigma}^t \xrightarrow{\text{Springer}} \check{\sigma}^t.$$

]

The $W_{[\lambda_{\check{\sigma}}]}$ -module $\text{Coh}_{[\lambda_{\check{\sigma}}]}$ is given by the following formula:

$$\begin{aligned} \text{Coh}_{[\lambda_{\check{\sigma}}]} &\cong \mathcal{C}_{n_e} \otimes \mathcal{C}_{n_o} \quad \text{with} \\ \mathcal{C}_n &:= \bigoplus_{\substack{s,a,b \\ 2s+a+b=n}} \text{Ind}_{W_s \times S_a \times S_b}^{S_n} \epsilon \otimes 1 \otimes 1. \end{aligned}$$

According to Vogan duality, we can obtain the above formula by tensoring sgn on the formula of the unitary groups in [8, Section 4].

By branching rules of the symmetric groups, $\text{Unip}_{\check{\sigma}}(G)$ can be parameterized by painted partition.

$$\text{PP}_{\check{\sigma}} = \{ \tau: \text{Box}(\check{\sigma}^t) \rightarrow \{ \bullet, c, d \} \mid \begin{array}{l} \text{"}\bullet\text{" occurs with even} \\ \text{multiplicity in each column} \end{array} \}.$$

[The typical diagram of all columns with even length $2c$ are

•	...	•	•	...	•
⋮	⋮	⋮	⋮	⋮	⋮
•	...	•	c	...	c
•	...	•	d	...	d

The typical diagram of all columns with odd length $2c + 1$ are

•	...	•	•	...	•
⋮	⋮	⋮	⋮	⋮	⋮
•	...	•	•	...	•
c	...	c	d	...	d

]

Let $\text{sgn}_n: \text{GL}_n(\mathbb{R}) \rightarrow \{ \pm 1 \}$ be the sign of determinant. Let 1_n be the trivial representation of $\text{GL}_n(\mathbb{R})$. For $\tau \in \text{PP}_{\check{\sigma}}$, we attach the representation

$$(3.1) \quad \pi_{\tau} := \bigtimes_j \underbrace{1_j \times \cdots \times 1_j}_{c_j\text{-terms}} \times \underbrace{\text{sgn}_j \times \cdots \times \text{sgn}_j}_{d_j\text{-terms}}.$$

Here

- j running over all column lengths in $\check{\mathcal{O}}^t$,
- d_j is the number of columns of length j ending with the symbol “d”,
- c_j is the number of columns of length j ending with the symbol “•” or “c”, and
- “ \times ” denote the parabolic induction.

3.3. Special Unipotent representations of $G = \mathrm{GL}_m(\mathbb{H})$. Suppose that \mathcal{O} is the complexification of a rational nilpotent $\mathrm{GL}_m(\mathbb{H})$ -orbit. Then \mathcal{O} has only even length columns. Therefore, $\mathrm{Unip}_{\check{\mathcal{O}}}(G) \neq \emptyset$ only if $\check{\mathcal{O}} = \check{\mathcal{O}}_e$.

In this case the coherent continuation representation is given by

$$\mathrm{Coh}_{[\lambda_{\check{\mathcal{O}}}]}(G) = \mathrm{Ind}_{W_m}^{S_{2m}} \epsilon$$

and $\mathrm{Unip}_{\check{\mathcal{O}}}(G)$ is a singleton. For each partition τ only having even columns, we define

$$\pi_{\tau} := \bigotimes_i 1_{\mathbf{c}_i(\tau)/2}.$$

3.4. Counting special unipotent representations of $\mathrm{U}(p, q)$. We call the parity of $|\check{\mathcal{O}}|$ the “good parity”. The other parity is called the “bad parity”. We write $\check{\mathcal{O}} = \check{\mathcal{O}}_g \cup \check{\mathcal{O}}_b$ where $\check{\mathcal{O}}_g$ and $\check{\mathcal{O}}_b$ consist of good parity length rows and bad parity rows respectively.

Let $(n_g, n_b) = (|\check{\mathcal{O}}_g|, |\check{\mathcal{O}}_b|)$. Now as the $S_{n_g} \times S_{n_b}$

$$\bigoplus_{\substack{p, q \in \mathbb{N} \\ p+q=n}} \mathrm{Coh}_{[\lambda_{\check{\mathcal{O}}}]}(\mathrm{U}(p, q)) = \mathcal{C}_{gd} \otimes \mathcal{C}_{bd}$$

where

$$\begin{aligned} \mathcal{C}_{gd} &= \bigoplus_{\substack{s, a, b \in \mathbb{N} \\ 2s+a+b=n_g}} \mathrm{Ind}_{W_s \times S_a \times S_b}^{S_{n_g}} 1 \otimes \mathrm{sgn} \otimes \mathrm{sgn} \\ \mathcal{C}_{bd} &= \begin{cases} \mathrm{Ind}_{W_{\frac{n_b}{2}}}^{S_{n_b}} 1 & \text{if } n_b \text{ is even} \\ 0 & \text{otherwise.} \end{cases} \end{aligned}$$

By the above formula, we have

Lemma 3.1. (i) The set $\mathrm{Unip}_{\check{\mathcal{O}}_b}(\mathrm{U}(p, q)) \neq \emptyset$ if and only if $p = q$ and each row length in $\check{\mathcal{O}}$ has even multiplicity.

(ii) Suppose $\mathrm{Unip}_{\check{\mathcal{O}}_b}(\mathrm{U}(p, p)) \neq \emptyset$, let $\check{\mathcal{O}}'$ be the Young diagram such that $\mathbf{r}_i(\check{\mathcal{O}}') = \mathbf{r}_{2i}(\check{\mathcal{O}}_b)$ and π' be the unique special unipotent representation in $\mathrm{Unip}_{\check{\mathcal{O}}'}(\mathrm{GL}_p(\mathbb{C}))$. Then the unique element in $\mathrm{Unip}_{\check{\mathcal{O}}_b}(\mathrm{U}(p, p))$ is given by

$$\pi := \mathrm{Ind}_P^{\mathrm{U}(p, p)} \pi'$$

where P is a parabolic subgroup in $\mathrm{U}(p, p)$ with Levi factor equals to $\mathrm{GL}_p(\mathbb{C})$.

(iii) In general, when $\mathrm{Unip}_{\check{\mathcal{O}}_b}(\mathrm{U}(p, p)) \neq \emptyset$, we have a natural bijection

$$\begin{aligned} \mathrm{Unip}_{\check{\mathcal{O}}_g}(\mathrm{U}(n_1, n_2)) &\longrightarrow \mathrm{Unip}_{\check{\mathcal{O}}}(\mathrm{U}(n_1 + p, n_2 + p)) \\ \pi_0 &\longmapsto \mathrm{Ind}_P^{\mathrm{U}(n_1+p, n_2+p)} \pi' \otimes \pi_0 \end{aligned}$$

where P is a parabolic subgroup with Levi factor $\mathrm{GL}_p(\mathbb{C}) \times \mathrm{U}(n_1, n_2)$.

The above lemma ensure us to reduce the problem to the case when $\check{\mathcal{O}} = \check{\mathcal{O}}_g$. Now assume $\check{\mathcal{O}} = \check{\mathcal{O}}_g$ and so $\mathrm{Coh}_{[\check{\mathcal{O}}]}$ corresponds to the blocks of the infinitesimal character of the trivial representation.

By [8, Theorem 4.2], Harish-Chandra cells in $\mathrm{Coh}_{[\check{\mathcal{O}}]}$ are in one-one correspondence to real nilpotent orbits in $\mathcal{O} := d_{\mathrm{BV}}(\check{\mathcal{O}}) = \check{\mathcal{O}}^t$.

[From the branching rule, the cell is parametered by painted partition

$$\text{PP}(\mathbf{U}) := \{ \tau \in \text{PP} \mid \begin{array}{l} \text{Im}(\tau) \subseteq \{ \bullet, s, r \} \\ \text{"}\bullet\text{" occurs even times in each row} \end{array} \}.$$

The bijection $\text{PP}(\mathbf{U}) \rightarrow \text{SYD}, \tau \mapsto \mathcal{O}$ is given by the following recipe: The shape of \mathcal{O} is the same as that of τ . \mathcal{O} is the unique (upto row switching) signed Young diagram such that

$$\mathcal{O}(i, \mathbf{r}_i(\tau)) := \begin{cases} +, & \text{when } \tau(i, \mathbf{r}_i(\tau)) = r; \\ -, & \text{otherwise, i.e. } \tau(i, \mathbf{r}_i(\tau)) \in \{ \bullet, s \}. \end{cases}$$

Example 3.2.

]

Now the following lemma is clear.

Lemma 3.3. *When $\check{\mathcal{O}} = \check{\mathcal{O}}_g$, the associated variety of every special unipotent representations in $\text{Unip}_{\check{\mathcal{O}}}(\mathbf{U})$ is irreducible. Moreover, the following map is a bijection.*

$$\begin{array}{ccc} \text{Unip}_{\check{\mathcal{O}}_g}(\mathbf{U}(n_1, n_2)) & \longrightarrow & \{ \text{rational forms of } \check{\mathcal{O}}^t \} \\ \pi_0 & \mapsto & \text{AV}^{\text{weak}}(\pi_0). \end{array}$$

□

Remark. When $\check{\mathcal{O}}_b \neq \emptyset$, the special unipotent representations can have reducible associated variety. Meanwhile, it is easy to see that the map $\text{Unip}_{\check{\mathcal{O}}}(\mathbf{U}) \ni \pi \mapsto \text{AV}^{\text{weak}}(\pi)$ is still injective.

We will show that every elements in $\text{Unip}_{\check{\mathcal{O}}_g}$ can be constructed by iterated theta lifting. For each τ , let \mathcal{O} be the corresponding real nilpotent orbit. Let $\text{Sign}(\mathcal{O})$ be the signature of \mathcal{O} , $\nabla(\mathcal{O})$ be the signed Young diagram obtained by deleting the first column of \mathcal{O} . Suppose \mathcal{O} has k -columns. Inductively we have a sequence of unitary groups $\mathbf{U}(p_i, q_i)$ with $(p_i, q_i) = \text{Sign}(\nabla^i(\mathcal{O}))$ for $i = 0, \dots, k$. Then

$$(3.2) \quad \pi_\tau = \theta_{\mathbf{U}(p_1, q_1)}^{\mathbf{U}(p_0, q_0)} \theta_{\mathbf{U}(p_2, q_2)}^{\mathbf{U}(p_1, q_1)} \cdots \theta_{\mathbf{U}(p_k, q_k)}^{\mathbf{U}(p_{k-1}, q_{k-1})}(1)$$

where 1 is the trivial representation of $\mathbf{U}(p_k, q_k)$.

Suppose $\check{\mathcal{O}} = \check{\mathcal{O}}_g$. Form the duality between cells of $\mathbf{U}(p, q)$ and $\text{GL}(n, \mathbb{R})$. We have an ad-hoc (bijective) duality between unipotent representations:

$$\begin{array}{ccc} d_{\text{BV}}: \text{Unip}_{\check{\mathcal{O}}}(\mathbf{U}) & \rightarrow & \text{Unip}_{\check{\mathcal{O}}^t}(\text{GL}(\mathbb{R})) \\ \pi_\tau & \mapsto & \pi_{d_{\text{BV}}(\tau)} \end{array}$$

Here $\check{\mathcal{O}}^t = d_{\text{BV}}(\check{\mathcal{O}})$ and $d_{\text{BV}}(\tau)$ is the painted bipartition obtained by transposing τ and replace s and r by c and d respectively. See (3.2) and (3.1) for the definition of special unipotent representations on the two sides.
